You are given an array of variable pairs `equations` and an array of real numbers `values`, where `equations[i] = [Ai, Bi]` and `values[i]` represent the equation `Ai / Bi = values[i]`. Each `Ai` or `Bi` is a string that represents a single variable.

You are also given some `queries`, where `queries[j] = [Cj, Dj]` represents the `jth` query where you must find the answer for `Cj / Dj = ?`.

Return the answers to all queries. If a single answer cannot be determined, return `-1.0`.

Note: The input is always valid. You may assume that evaluating the queries will not result in division by zero and that there is no contradiction.

Example 1:

Input: `equations = [["a","b"],["b","c"]]`, `values = [2.0,3.0]`, `queries = [["a","c"],["b","a"],["a","e"],["a","a"],["x","x"]]`

Output: `[6.00000,0.50000,-1.00000,1.00000,-1.00000]`

Explanation:

Given: `a / b = 2.0`, `b / c = 3.0`

queries are: `a / c = ?`, `b / a = ?`, `a / e = ?`, `a / a = ?`, `x / x = ?`

return: `[6.0, 0.5, -1.0, 1.0, -1.0]`
